

**SUBJECT** : **Cabin Evacuation - Protection from Fuel Tank Explosion due to External Fuel Fed Ground Fire**

**REQUIREMENTS incl. Amdt.** : **CS 25.863, 25.867, 25.975(a)(7), 25.981(a)(1) and (2) and 25.963(e)(2) at Amendment 22**

**ASSOCIATED IM/MoC<sup>1</sup>** : Yes  / No

**ADVISORY MATERIAL** : **AMC 25.863(a), AMC 25.963(e), AMC 25.975(a)(7)**

#### INTRODUCTORY NOTE:

The following Special Condition (SC) has been classified as important and as such shall be subject to public consultation in accordance with EASA Management Board decision 12/2007 dated 11 September 2007, Article 3 (2.) which states:

*"2. Deviations from the applicable airworthiness codes, environmental protection certification specifications and/or acceptable means of compliance with Part 21, as well as important special conditions and equivalent safety findings, shall be submitted to the panel of experts and be subject to a public consultation of at least 3 weeks, except if they have been previously agreed and published in the Official Publication of the Agency. The final decision shall be published in the Official Publication of the Agency."*

#### IDENTIFICATION OF ISSUE:

EASA received an application for a major change to type design on a large aeroplane.

- 1) The design change introduces a conformal fuselage structural fuel tank<sup>2</sup> to the aeroplane, also called rear centre tank (RCT) located behind the wheel bay, in the lower section of the fuselage, partially replacing the aft cargo compartment.

The integration of a conformal fuselage structural fuel tank located below the cabin floor presents challenges in terms of occupants protection against the risks of external fire burnthrough, fuel vapour ignition and fuel tank explosion as well as challenges to ensure crashworthiness of this fuel tank. The protection against external fire burnthrough was addressed through another Special Condition that was published by EASA earlier:

<https://www.easa.europa.eu/document-library/product-certification-consultations/final-special-condition-ref-sc-d25856-01>

The crashworthiness of this fuel tank design will be addressed by a dedicated Special Condition at a later stage.

This SC therefore addresses only the risk of fuel ignition and fuel tank explosion.

<sup>1</sup> In case of SC, the associated Interpretative Material and/or Means of Compliance may be published for awareness only and they are not subject to public consultation.

<sup>2</sup> Conformal fuselage structural fuel tank: A structural fuselage fuel tank, that shares some boundaries with the fuselage skin.

The experience gathered with large aeroplanes carrying more than 19 passengers, equipped with classical wing fuel tanks (incl. centre wing fuel tanks) and auxiliary tanks located in cargo compartments, is considered satisfactory in terms of protection of the cabin occupants during post crash evacuation from the risk of fuel tank explosion generated by an external fuel fed ground fire. However, the proposed RCT installation, because of its design and location, is considered as an unusual or novel design feature for this category of aeroplanes with regards to this risk.

- 2) The CS-25 at Amendment 22 includes several specifications that address the risk of fuel vapours ignition. However, none of them adequately covers the risk of ignition in a RCT as introduced on this aeroplane in case of external fuel fed ground fire:
- CS 25.863 considers the minimisation of the probability of ignition and resultant hazards due to the ignition of flammable fluids or vapours that might escape from a fluid system.
  - CS 25.867 considers the fire protection in specific zones around the nacelle.
  - CS 25.963(e)(2) requires the Fuel Tank Access Covers to *“have the capacity to withstand the heat associated with fire at least as well as an access cover made from aluminium alloy in dimensions appropriate for the purpose for which they are to be used except that the access covers need not be more resistant to fire than an access cover made from the base fuel tank structural material.”* This rule was created following [an accident where a fuel tank access panel failed from impact damage causing a fuel leak from a perforated wing tank and generated an external fuel fed ground fire.](#)
  - CS 25.975(a)(7) specifies that fuel tank vent systems must prevent explosions, for a minimum of 2 minutes and 30 seconds, in case of external ground fire.
  - CS 25.981(a)(1) and (2) require to demonstrate that no aircraft systems operation, failure, malfunction may cause an increase of temperature inside the fuel tank beyond a temperature that has a safe margin below the lowest expected auto-ignition temperature of the fuel.

The inerting of the fuselage tank, while introduced in the frame of compliance with CS 25.981(b), is primarily focussed at protecting the fuel tank against internal design failure modes that could ignite fuel vapours. Moreover, the agreed compliance means of the inerting system is based on a statistical objective following a Monte-Carlo analysis per CS-25 Appendix N. This strategy cannot be assumed to meet the safety objective of protection against external ground fire hazards.

However, Flammability Reduction Systems or Ignition Mitigation Means can be considered provided their performance could be demonstrated to prevent ignition of RCT fuel vapours by an external ground fire. In accordance with 21.B.75(a)(1) of Annex Part-21 to Regulation (EU) 748/2012 for novel or unusual design features, there is the need to address the threat of RCT fuel vapour ignition in case of external fuel fed ground fire.

Considering all the above, the following Special Condition is proposed:

**Special Condition****Cabin Evacuation - Protection from Conformal Fuselage Structural Fuel Tank Explosion due to External Fuel Fed Ground Fire**

In order to protect cabin occupants during evacuation, from the risk of fuselage tank explosion triggered by an external fuel fed ground fire<sup>3</sup>, the large aeroplane design must prevent **ignition of fuel tank vapour (due to hot surface)** from occurring inside the conformal fuselage structural fuel tank.

The corresponding demonstration must consider sufficient time to allow a safe evacuation of all occupants after an event leading to an external fuel fed ground fire.

**Definition**

A conformal fuselage structural fuel tank is a fuel tank, that shares some boundaries with the fuselage skin.

---

<sup>3</sup> External fuel fed ground fire: An external fuel fed ground fire or external fuel fed pool fire will be referred to 'external ground fire' later in the IM and MoC part for sake of brevity.

**Interpretative Material to Special Condition SC-D25.863-01**

The associated Interpretative Material is published for awareness only and is not subject to public consultation.

**Fuel Vapours ignition conditions for a fuel tank explosion**

The risk of explosion due to an external ground fire arises from fuel vapours within the tank coming into contact with the heated tank surface (hot surface ignition risk). The applicant may use a time to reach 204 °C (400 °F) on the inner side of the tank wall as the criteria for determining the ignition condition. This 204 °C (400 °F) temperature value is accepted by EASA as the maximum surface temperature inside fuel tanks for kerosene type fuels without further substantiation (reference to AMC 25.981(a)). A transient excursion for not more than 2 minutes above 204 °C (400 °F) but remaining below the accepted auto-ignition temperature of 232 °C (450 °F) for kerosene type fuels is also accepted, in accordance with AMC 25.981 §3.5.3 conditions. A higher surface temperature threshold and/or longer excursion time may be used but will need to be substantiated.

### **Means of Compliance to Special Condition SC-D25.863-01**

The associated Means of Compliance are published for awareness only and are not subject to public consultation.

#### **1 - Time duration for fuel vapours ignition prevention**

In order to comply with the Special Condition requirement, the applicant should demonstrate that the conditions allowing the ignition of the conformal fuselage structural tank fuel vapours are not reached during at least 5 minutes of exposure to the external ground fire.

#### **2 - Baseline minimum time to vapour ignition**

The above minimum time of 5 minutes is derived from the CS 25.856(b) objective for fire burnthrough prevention. It is deemed adequate to allow safe evacuation of occupants.

The applicant should consider the same safety objective for the emergency evacuation for all external ground fire generated hazards. Therefore, this time duration is also used as the baseline standard for fuselage tank fuel vapours ignition protection.

#### **3 - Evaluation conditions for the conformal fuselage structural fuel tank**

The demonstration should be based on tests or analysis supported by tests.

The test or analysis supported by test should consider critical fuel loads for the risk of explosion.

The test or analysis supported by test should include the most critical design sections or parts of the fuel tank for the fuel vapour ignition conditions.

#### **4 - External fuel fed Ground Fire Flame definition**

The time needed to reach the fuel vapour ignition conditions on the inner surface of the fuselage structural fuel tank wall should be established using a representative flame characterizing external ground fire conditions.

CS 25 Appendix F, Part VII specifies a test method to determine the burnthrough resistance of thermal/acoustic insulation materials. This includes the specifications for a test burner representing, during material burnthrough tests, an external ground fire impacting the fuselage.

For the demonstration of compliance of a conformal fuselage tank with the present Special Condition, the applicant may either use a burner complying with the Appendix F, Part VII specifications, or a burner providing the same flame characteristics.
